Title Of Invention

**METHOD AND SYSTEM FOR ELECTRONIC COMMERCE USING PRODUCTS
SATISFACTION INDEX**

CROSS-REFERENCES TO RELATED APPLICATIONS

[0001] This application is a continuation of pending International Patent Application No. PCT/KR02/00395 filed March 7, 2002, which designates the United States and claims priority of pending Korean Application Nos. 2001/11593, filed March 7, 2001 and 2001/88497 filed December 29, 2001.

BACKGROUND OF THE INVENTION

Field Of The Invention

[0002] The present invention relates to a method and system for an electronic commerce employing a products satisfaction index, and more particularly, to a method and system for an electronic commerce capable of satisfying both of a purchaser and a seller by computing a products satisfaction index with reference to products information provided by the seller and purchasing conditions provided by the purchaser, and computing a purchase satisfaction price on the basis of the products satisfaction index.

Description of the Related Art

[0003] Generally, in case of retrieving products to carry out electric commerce over Internet, since the electric commerce is based on some purchasing conditions such as a product name, a price condition and so forth,

other products unsuitable for the purchasing conditions of a purchaser are unnecessarily arranged.

[0004] Accordingly, since the purchaser has to retrieve the wanted products one by one, a lot of time is wasted. In addition, there are some cases in that the purchaser does not find the wanted products.

[0005] In order to solve the problem, many Internet sites come into being. Some of the Internet sites require others or visitors to input an optional satisfaction value for purchasing condition related to quality, price, transit, returns, and other service items of the product, thereby evaluating the product. To this end, the operator has to maintain transparency, such as neutrality, objectivity, fairness, and so forth, upon operating the site. However, a seller or party concerned attempts to increase the value of the products by using inadequate means or methods.

[0006] Furthermore, since these methods do not reflect the purchasing conditions for a group of wanted products wanted by the purchaser, the retrieving means is not accurate in a position of the purchaser.

[0007] The evaluation of the product by the basis of the purchaser is one of benefits provided to the purchaser on the Internet, but it is an important factor how much does the purchaser confide in the evaluations of the others on the group of the products.

[0008] The methods for electronic commerce on the Internet include cyber shopping, general auction, reverse auction, joint purchase and so forth. Most of them are a stiff price determining system in which the trade is achieved based on the price presented by only one side such as seller or purchaser, but there is another price determining system capable of transacting the trade by achieving the price determination at a price level that

satisfies both of the seller and purchaser. In particular, in the electronic commerce transacting the trade in which the purchaser offers the selling price, like an Internet shopping mall providing the general auction or reverse auction, in case that the purchase offering price of the purchaser is not reasonable, the seller does not sell the product for a low contact price, but tries to employ every conceivable means and method to increase the contact price. Occasionally, even if the product is sold at the purchase offering price presented by the purchaser, the seller pulls up with an extraordinary loss. In addition, the purchaser, the seller and the operator of the Internet site wait up to a closing time every case, and cannot undertake anything. Accordingly, all of them suffer from the unreasonable electronic commerce.

SUMMARY OF THE INVENTION

[0009] Therefore, an object of the present invention is to solve the problems involved in the conventional art, and to provide an electronic commerce method capable of evaluating values of individual product and retrieving the product on the basis of the values by quantitatively normalizing how much does individual product to be sold by the seller satisfy all of the purchasing conditions for the product to be purchased.

[0010] Another object of the present invention is to provide an electronic commerce method capable of utilizing a reasonable purchase offering price when purchasing the product by applying the value for individual product of the purchaser to the selling price to compute a price satisfying the purchaser.

[0011] A value evaluation of a product is indicative of a price of the product as following. The product is one result produced or manufactured to satisfy purchasing conditions of the purchaser, and a product price is a price

for satisfying all of purchasing conditions of the purchaser for the product, which will be expressed as a below equation 1:

$$P_s = P_1 + P_2 + \dots + P_n$$

$$= \sum_{k=1}^n P_k$$

[00012] wherein, P_s is the selling price of the product, and P_k is the price for a value satisfying one purchasing condition of the purchaser related to the product.

[00013] Since the selling price (P_s) of the product is the total sum of the prices (P_k) for the value satisfying one purchasing condition of the purchaser related to the product, there is a close relationship between an entity of the product, such as a characteristic or property of the product, and various purchasing conditions of the purchaser.

[00014] Therefore, the relationship between various purchasing conditions of the purchaser and the entity of the product is represented by one unified value, which is similar to that a degree of satisfaction of the purchaser for individual product is represented by a value. To this end, there is required a normalized and unified input format in processing various data of the seller and purchaser, and also an operator for providing and managing it.

[00015] The operator prepares a standardized and unified input format for standard items on factors capable of being regarded as the purchasing condition of the purchaser, and particulars of the respective standard items, relative to the entity of the product such as individual characteristic or property of the all products to be purchased, thereby making a purchasing condition database. The operator provides the seller with a request of products information registration, which is prepared by extracting

the purchasing condition of the purchaser related to the product to be purchased by the seller. A products information database is made for the contents inputted through the request of products information registration, in which each of the standard items is a field name of the products information database, and the particulars for the standard items consist of the contents of actual products information. The products information is not arbitrarily inputted by the seller, but is inputted by the contents suitable for the characteristic of the product, which is to be purchased by the seller, through sample data adapted to the input format provided by the operator.

[00016] The operator provides the purchaser with an input sheet, which is prepared by extracting the purchasing conditions related to the product name wanted by the purchaser from the purchasing condition database, so that the purchaser inputs the contents suitable for his or her purchasing conditions. Upon retrieving the product, since the purchasing condition provided by the purchaser can be compared with the fields of the products information database, a value of products satisfaction index (PSI) can be obtained by operation. The operator compares the contents inputted by the purchaser with the contents of the products information, and shows the purchaser the results as the value of the product satisfaction index.

[00017] Since the products satisfaction index is a total index indicative of the products for the purchasing conditions of the purchaser, the product retrieve is easily performed by use of only the value, so that a target product can be easily, quickly and exactly found, contrary to the conventional method of individually retrieving the target product among a group of the products retrieved by some purchasing conditions such as a price condition.

[00018] Even though the selling price can be satisfied in a position of the seller, the satisfaction of the purchasers relative to the selling price of the product is different from each other since the purchasing conditions are

different from every individual. Therefore, it is necessary for the operator to know how does each purchaser approve the product to be sold by the seller and how much be the selling price sold to satisfy the purchaser.

[00019] Accordingly, the present invention provides a method of computing a price satisfying the purchaser, i.e., a purchase satisfaction price (PSP), which is computed by multiplying the purchasing satisfaction index for the individual product by the selling price. Since the purchase satisfaction price is determined by both the purchaser and the seller, they are quite satisfied with that price, so that the purchase satisfaction price may be utilized as a purchase offering price. In addition, it is easy to select the products by displaying it together with the products satisfaction index.

[00020] If the products dissatisfaction index is computed on the based of the products satisfaction index and is applied to the selling price, a reduced price can be obtained for reducing a degree of the dissatisfaction for the product. The purchasing possibility may be increased by applying it to the electronic commerce, and the selling promotion of the seller and the profits increase of the site operator may be achieved.

[00021] In particular, the present invention introduces a sale approval price, so that the seller can flexibly manage the price. Therefore, the seller copes easily with the purchase satisfaction price of the purchaser, and frees from the competitive pricing with the product of other company. Also, it is possible to prevent the violation of a commercial transaction of the seller relative to a lower contract price of the purchaser.

[00022] Furthermore, since the system of the present invention connects from the products information retrieve to the product purchase directly, it may prevent the purchaser from breaking away from the site. The sellers regulates the minimum selling approval price on the basis of the

products satisfaction index at any time, so that a latent purchasing client can be directly connected to the purchase. Since various purchasing conditions of the purchaser are applied to the sales product of the seller, statistical data and information usable in the object economy may be provided to the manufactures, the producers, the distributors and other company starting a new business.

[00023] It is to be understood that both the foregoing general description and the following detailed description of the present invention are exemplary and explanatory and are intended to provide further explanation of the present invention as claimed.

BRIEF DESCRIPTION OF THE DRAWINGS

[00024] The above objects, other features and advantages of the present invention will become more apparent by describing the preferred embodiment thereof with reference to the accompanying drawings, in which:

[00025] Fig. 1 is a network diagram of an electronic commercial system applied to the present invention.

[00026] Fig. 2 is a block diagram of the operation server according to the present invention.

[00033] Fig. 9 is a flowchart explaining a process of reusing the purchasing specification information of the present invention.

[00034] Fig. 10 shows an example of an initial screen displayed on a display unit of the seller or the purchaser.

[00035] Fig. 11A shows a request of products information registration inputted by seller according to an embodiment of the present invention.

[00036] Fig. 11B shows an example of a minimum sale approval price according to the products satisfaction index in Fig. 11A.

[00037] Fig. 12A shows a basic purchasing condition input sheet of a purchaser according to an embodiment of the present invention.

[00038] Fig. 12B shows an example of products information provided in case of clicking a detail retrieving button of the basic purchasing condition input sheet in Fig. 12A.

[00039] Fig. 12C shows a detailed purchasing condition input sheet according to an embodiment of the present invention.

[00040] Fig. 13 shows a classification table of various purchasing conditions related to products selection criteria items and comparative prominent items of a product "shirt" according to an embodiment of the present invention.

[00041] Fig. 14A shows a sub-menu provided in case of selecting a retrieved item in Fig. 10.

[00042] Fig. 14B shows an example of a retrieved result displayed on a screen when inputting a single purchasing condition in Fig. 10.

[00043] Fig. 15A shows a comparative specification indicative of a retrieved result on the basis of a products satisfaction index according to an embodiment of the present invention.

[00044] Fig. 15B shows a comparative specification in which the comparative specification in Fig. 15A is rearranged on the basis of a priority of a purchasing condition according to an embodiment of the present invention.

[00045] Fig. 16 shows a screen displaying a detail purchasing condition input sheet in which an initial value for products information is mentioned when clicking a product icon according to an embodiment of the present invention.

[00046] Fig. 17 shows a sub-menu displayed in case of selecting purchasing specification inquiring items in Fig. 10.

DETAILED DESCRIPTION OF THE DRAWINGS

[00047] Reference will now be made in detail to the preferred embodiment of the present invention.

[00048] Now, preferred embodiments of the present invention will be described in detail with reference to the annexed drawings. A sales product of a seller applied to the present invention comprises all of items (hereinafter referred to as "products") of which business transactions are carried out over Internet, such as natural products, products, services, ideas, information, and several marketable securities (e.g., gift certificates, advance tickets, stocks, bonds and so forth).

[00049] Fig. 1 is a network diagram of an electronic commercial system applied to the present invention.

[00050] As shown in Fig.1, a purchaser client 100 and a seller client 300 can access to an operation server 400 over Internet 200, respectively.

[00051] The purchaser client 100, the seller client 300, and the operation server 400 comprise a computer system or cable and wireless terminal having a proper Web browser, respectively.

[00052] Fig. 2 is a block diagram of the operation server according to the present invention.

[00053] Information on items of a purchasing condition input sheet provided to the purchaser and detailed information related to each item are stored in a purchasing condition database 468 every product. Products information input module 415 extracts items capable of being regarded as the purchasing conditions of the purchaser related to the product which is to be sold by the seller, from the purchasing condition database 468 to prepare a request of products information registration, and the request of products information registration is provided to the seller, so that the products information is stored in the products information database 466.

[00054] A purchasing condition input module 425 provides a purchasing condition input sheet related to a first retrieved product to the purchaser to input a basic purchasing condition and a detailed purchasing condition.

[00055] A member manage module 430 receives personal information from the purchaser and the seller, and stores it in a purchaser member information database 462 and a seller member information database 464, respectively.

[00056] A products satisfaction index computing module 420 compares the products information stored by the seller with the purchasing condition inputted by the purchaser to compute products satisfaction index of individual product.

[00057] A purchasing satisfaction condition computing module 440 computes a purchasing satisfaction condition on the basis of the computed products satisfaction index.

[00058] A retrieve module 450 receives a name of the product and the price condition, and performs the first retrieve. And then, the retrieve module 450 performs the second retrieve in accordance with several purchasing conditions, the third retrieve in accordance with the products satisfaction index, and the final retrieve in accordance with the purchasing condition priorities, respectively.

[00059] A purchase approval module 460 determines whether the purchasing satisfaction condition of the product selected by the purchaser belongs to a range of sale approval price of the seller, based on the final retrieve, displays the results of the purchase approval on a screen, and stores the purchasing specification in the purchasing specification database 470.

[00060] A control module 410 controls a data stream between modules and the storage and output of the data from the databases.

[00061] Fig. 3 is a flowchart of the electric commerce process according to the present invention.

[00062] Referring to Fig. 3, in a basic data processing step S100, the member information related to the purchaser and the seller is inputted and stored in the seller and the purchaser member information databases. The products information inputted from the seller is stored in the products information database.

[00063] In a first product retrieving step S200, the product name to be purchased and the price condition are inputted to show them to the purchaser.

[00064] In a products satisfaction index computing step S300, it compares the products information inputted by the seller with several purchasing conditions inputted by the purchaser regarding to the first retrieved product to compute the products satisfaction index of individual product and thus compute the purchasing satisfaction condition.

[00065] In a final retrieving step S400, the final retrieve is performed by inputting a value of the products satisfaction index, otherwise the final retrieve is preferably added in accordance with the priority of the purchasing condition. Alternatively, the product retrieve is finally performed by simultaneously comparing individual characteristic or property of the whole group of products to be retrieved according to a single purchasing condition.

[00066] In a purchase approval processing step S500, it compares a purchase offer price with a purchase satisfaction price and a minimum

purchase approvable price according to the products satisfaction index, thereby admitting the purchase.

[00067] The steps described above will now be explained in detail.

[00068] Fig. 4 is a flowchart explaining the basic data processing process.

[00069] First, an operator prepares a standardized and unified input format for standard items on factors capable of being regarded as the purchasing condition of the purchaser, and particulars of each standard items, relative to the entity of the product such as individual characteristic or property of the all products to be purchased, thereby making the purchasing condition database 468.(step S110)

[00070] The operator provides the seller with the request of products information registration, which is prepared by extracting the purchasing condition of the purchaser related to the product to be purchased by the seller (step S120).

[00071] If the seller accesses to the operation server and inputs an identification and a password of the seller, the member managing module of the operation server transfers the member information to the control module to determine whether the seller is a member based on the member information stored in the seller member information database. If no the seller is the member, a message for joining a member is displayed.

[00072] The seller member information database comprises, for example, a seller's ID, a name of a company, a number of business registration, a name of a representation, a number of social security of the representation, a name of a Web site, an e-mail address, a telephone

number, an address, a state, a kind of business (e.g., a large enterprise, a small-medium industry, a venture, an individual and so forth), a capital, the number of employs, a year of the establishment of company, sales products, a registration date, and so forth, as a field.

[00073] If it is identified as a member, the seller inputs various products information to be sold (step S130). The operation server provides the seller with the request of products information registration on-line to obtain the products information, as shown in Fig. 11A, and the inputted information is stored in the products information database 470. As described below, the field of the products information database is adapted to be correspondent to various purchasing conditions of the purchaser, so that it is possible to compare it with the purchasing condition of the purchaser, thereby computing the products satisfaction index.

[00074] Each field of the products information database includes various particulars composed of a proper noun, a common noun and numerals suitable for the characteristic of each field. For example, in case of clothing, it is provided on a material of the product, which is a standard of an objective judgment, with a format of the proper or common noun such as "natural fiber (cotton, wool, leather and so forth)", "chemical fiber (nylon, synthetic resin and so forth)", "compound fiber", or the like. Otherwise, it is provided on the elasticity of the product, which is a standard of a future-oriented, abstractive or subjective judgment, with a format of a verbal noun such as "good", "common", "bad", or the like, the common noun such as "good", "commonness", "badness", or the like, or the numerals indicative of its size such as "3", "2", "1", or the like.

[00075] If the purchaser accesses to the operation server and inputs the ID and password of the seller, the member managing module of the operation server transfers the member information to the control module,

thereby determining whether the seller is a member based on the member information stored in the seller member information database. If no the seller is the member, a message for joining a member is displayed.

[00076] The fields of the purchaser member information database comprises an ID, a name, a social security number, a sex, an age, an address, a telephone number, a mobile number, an e-mail address, a school education, an interest, a special skill, an occupation, a joining data and the like. If it is identified as the member, the purchaser can be provided with services of the products information retrieve and the electro commerce.

[00077] Fig. 5 is a flowchart explaining the first product retrieving process.

[00078] First, the operation server receives the ID and password from the accessed purchaser to check whether the purchaser is a member or not (step S210).

[00079] Keywords inputted for first retrieving the product are its name and price condition. In case of knowing both of them, the name and price condition are simultaneously inputted to perform the retrieve (step S220). The purchaser inputs directly the name and price condition, or inputs indirectly them by selecting product icon corresponding to the wanted name and price.

[00080] In case of no knowing the price condition, if the purchaser inputs the name of the product (step S230), minimum and maximum prices set to the corresponding product are displayed, so that the purchaser selects one among them or inputs directly the price condition (step S235).

[00081] In addition, in case of no knowing the name of the product, if the purchaser inputs the price condition (step S240), the names of the product

corresponding to the price condition are displayed, so that the purchaser selects one among them (step S245).

[00082] If the name and price condition of the product are inputted for the first product retrieve through the method as described above, the corresponding products information is extracted from the products information database and is displayed (step S250).

[00083] Fig. 6 is a flowchart illustrating the products satisfaction index computing process according to the present invention.

[00084] First, the basic purchasing condition related to the product retrieved first is inputted (step S310).

[00085] The purchasing condition is classified into the basic purchasing condition and the detailed purchasing condition. The basic purchasing condition comprises the conditions related directly to the purchaser, for example, an appearance (e.g., physical conditions), an age, a sex, a marriage, an occupation, an usage and the like. The detailed purchasing condition comprises the conditions related directly to the characteristic or property of the product, and the conditions related to a manufacturer and seller such as a quality, a function, a design, a color, a kind of product, conditions of delivery, payment terms and the like. The total purchasing condition items is stored in fields of the purchasing condition database. If the product to be purchased is selected through the first retrieve, the items corresponding to that are extracted from the purchasing condition database, and are provided to the purchaser in a type of the input sheet as shown in Fig. 12A.

[00086] If the input is completed as described, the retrieve on the product is performed based on the basic purchasing condition (step S315),

and the selected products are displayed on the screen according to the retrieve results (step S320).

[00087] And then, it is determined whether it proceeds to the product retrieve based on the products satisfaction index (step S325), and in case of progressing the product retrieve, the products information is provided according to the basic purchasing condition (step S330).

[00088] The products information comprises a portion of conditions composed of well-sold products, a new product, conditions related directly to the characteristic or property of the product, and purchasing conditions related to the manufacturer and seller such as a quality, a function, a design, a color, a kind of product, conditions of delivery, payment terms and the like,

[00089] The purchaser inputs the detailed purchasing condition with reference to the products information.(step S335) For example, if the purchaser wants the information on the well-sold products among the basic purchasing condition, statistics of such the information is prepared by the purchasing specification database, and the particulars of various purchasing condition items are checked off on the detailed purchasing condition input sheet, as shown in Fig. 12C. If there is any item no suitable to the propensity to purchase of the purchaser, the purchaser may modify the particulars of each purchasing condition item.

[00090] The products satisfaction index (PSI) of products which is first retrieved by the inputted purchasing conditions is computed (step S340).

[00091] The computation of the products satisfaction index of the first retrieve product on the basis of various purchasing conditions is represented by means of numerical values by grasping the number of elements common to the elements related to the entity of the product and the purchasing

condition of the purchaser. The products satisfaction index is computed by comparing the products information database for a group of the product retrieved by the first product retrieve with the purchasing condition input sheet inputted by the purchaser. The products satisfaction index may be computed by two methods, for example, a ratio method and a weight applying method. The values of the products satisfaction index computed by the above method are displayed together with the item of the retrieved product. Since the purchaser can judge all of individual product using the value only, the products satisfaction index is useful to the product retrieve.

[00092] It will now be explained on a kind of method of computing the products satisfaction index.

[00093] 1. Ratio method

[00094] The products satisfaction index means a percentage of the number of the purchasing condition items identical to fields of the products information database over the total purchasing condition items of the purchaser, which will be expressed as a below equation 2:

$$Is = (Nc / Nt) \times 100$$

[00095] wherein, Is is the products satisfaction index, Nc is the number of the purchasing condition items identical to fields of the products information database, and Nt is the total purchasing condition items of the purchaser.

[00096] 2. Weight applying method

[00097] The seller manufactures and sells the products predominant over the products of other company, in view of some items which belong to the purchasing conditions of the purchaser relative to the product to be sold

by the seller. The purchaser has a standard of selecting the products, i.e., some items to be duly considered when purchasing the products. The method computes the products satisfaction index by weighting the items identical to both conditions of the seller and purchaser, and specifically the products satisfaction index is computed by reflecting the will of the seller and purchaser simultaneously. In case that the contents of “predominant item” of the fields of the products information database of the seller is identical to that of the item of “product selection criteria” among the purchasing condition items of the purchaser, the ratio method is applied by weighting the purchasing condition item corresponding to the “predominant item” at several times relative to a common purchasing condition item. This method will be expressed as a below equation 3:

$$Is = \{ (xNcs + Nct) / (xNs + (Nt - Ns)) \} \times 100$$

[00098] wherein, Is is the products satisfaction index, Ncs is the number of the purchasing conditions in case that the contents of “predominant item” of the products information database is identical to that of the item of “product selection criteria” among the purchasing condition items, Nct is the number of the purchasing condition items in case that the contents of “predominant item” of the products information database is no identical to that of the item of “product selection criteria” among the purchasing condition items, Ns is the number of purchasing condition items related to the “predominant item” of the products information database and the “product selection criteria” items among the purchasing condition items, Nt is the total purchasing condition items of the purchaser, and x is a weight on each item of which the contents is identical between the number of purchasing condition items related to the “predominant item” of the products information database and the “product selection criteria” items among the purchasing condition items.

[00099] According to products dissatisfaction index (I_u) contrary to the products satisfaction index, it is represented as a value to what extent the individual product to be sold by the seller satisfies the whole purchasing conditions for the product to be retrieved by the purchaser. The products dissatisfaction index means a ratio of the number (N_u) of inconsistent items between the fields of the products information database and the purchasing condition items over the total items (N_t). In addition, in case that individual product to be sold by the purchaser satisfies all of the purchasing conditions for the products to be retrieved by the purchaser, the products dissatisfaction index is represented by a value obtained by subtracting the products satisfaction index from 100 of the maximum products satisfaction index, which will be expressed as a below equation 4:

$$I_u = (N_u / N_t) \times 100 = 100 - I_s$$

[000100] wherein, I_u is the products dissatisfaction index, N_u is a ratio of the number of inconsistent items between the fields of the products information database and the purchasing condition items over the total items, N_t is the total purchasing condition items of the purchaser, and I_s is the products satisfaction index.

[000101] If the products satisfaction index is computed as described above, the purchasing satisfaction condition is computed depending upon the computed products satisfaction index.(step S345)

[000102] The products satisfaction index evaluates the value of the product by use of indexes on behalf of the purchaser and the product. If the products satisfaction index is applied to the selling price of the seller, the price is reasonable to the product of the seller in a position of the purchaser. Accordingly, it is a purchasing satisfaction condition of the purchaser, and so may be used as a purchase offering price at the electron commerce. The

purchasing satisfaction condition may be computed by use of a method using the products satisfaction index and a method using the products dissatisfaction index, and will be now described hereinafter.

[000103] 1. Method using the products satisfaction index

[000104] The purchase satisfaction price (P_{sp}) means a price computed by multiplying a selling price (P_s) of individual product by the products satisfaction index (I_s) of the purchaser on the product, which will be expressed as a below equation 5:

$$P_{sp} = P_s \times I_s$$

[000105] wherein, P_{sp} is the purchasing satisfaction condition, P_s is the selling price of individual product, and I_s is the products satisfaction index.

[000106] 2. Method using the products dissatisfaction index

[000107] The purchase satisfaction price (P_{sp}) according to the products dissatisfaction index is a price obtained from computing the selling price (P_s) of individual product in terms of a reduced price (P_r) corresponding to the product dissatisfaction price and subtracting the reduced price from the selling price, which will be expressed as a below equation 6:

$$P_{sp} = P_s - P_r = P_s - \{P_s \times (100 - I_s)\} / 100 = P_s - (P_s \times I_u) / 100$$

[000108] wherein, P_{sp} is the purchasing satisfaction condition, P_s is the selling price of individual product, P_r is the reduced price, I_s is the products satisfaction index, and I_u is the products dissatisfaction index.

[000109] After computing the products satisfaction index and the purchasing satisfaction condition, the product retrieve is performed (step

S350), and a comparative specification is prepared (step S355). Specifically, the comparative specification including several major items such as the products satisfaction index and the purchasing satisfaction condition for the first retrieved products, as well as the information on individual product is prepared and provided to the purchaser, so that the purchaser can compare and consider the information on the retrieved results. The comparative specification includes a brand, a company name, the products satisfaction index, the purchasing satisfaction condition, the products dissatisfaction index, the selling price, factors of product dissatisfaction, and is arranged and displayed in order of a magnitude of the products satisfaction index. The factors of product dissatisfaction consist of the inconsistent items between items of the purchasing condition input sheet and the products information database, and are displayed so that the purchaser may refer to them when retrieving or purchasing the products.

[000110] Fig. 7 shows a flowchart illustrating a final product retrieving process in Fig. 3.

[000111] First, if the computed numeric value of the products satisfaction index is inputted (step S410), the products belonging to a range above the numeric value of the products satisfaction index inputted for the group of the first retrieved products are rearranged and displayed (step S420).

[000112] It determines whether the final product retrieve is to be performed depending upon the priority of the purchasing condition (step S430), and in case of no performing the final product retrieve, it proceeds to the purchase. Meanwhile, in case of performing the final product retrieve, if the priority of the purchasing condition is inputted (step S440), the product retrieve is again performed (step S450), and the results of the final retrieve are displayed (step S460). However high the products satisfaction index for the retrieved product based on the numeric value of the products satisfaction

index, if it does not coincide with some of the purchasing condition items which are considered as an importance to the purchaser, no the product may be one needed by the purchaser. Therefore, the final retrieve may be performed on the basis of the priority to various purchasing condition items previously inputted by the purchaser.

[000113] In addition, if a single purchasing condition is inputted, the particulars of the purchasing condition items corresponding to the whole group of the products are extracted from the products information database, and the contents is displayed on the screen, thereby retrieving the final product (step S470).

[000114] Fig. 8 is a flowchart illustrating a purchase approval process in Fig. 3.

[000115] If the purchaser selects the product to be purchased (step S510), it determines whether the purchasing satisfaction condition of the selected product belongs to a range of the sale approval price of the products information database of the seller (step S520). If the purchasing satisfaction condition of the selected product belongs to a range of the sale approval price, the order specification is identified (step S550). After it reports the delivery of the product to the seller (step S550), the purchasing specification is stored in the purchasing specification database (step S570).

[000116] If no the purchasing satisfaction condition of the selected product belongs to a range of sale approval price, the minimum sale approval price is presented from the products information database depending upon the products satisfaction index (step S530), and the purchaser again determines whether to purchase or not (step S540). After all, the purchasing satisfaction condition and the minimum sale approval price are a buying and selling price between the purchaser and the seller. If the minimum sale

approval price is readily utilized depending upon the products satisfaction index, a latent purchasing client can be directly connected to the purchase. Therefore, it becomes means of an important price policy.

[000117] Fig. 9 is a flowchart explaining a process of reusing the purchasing specification information.

[000118] If it determines whether the purchaser is a member(step S610), the purchasing specification previously stored is called from the purchasing specification information database (step S620), and the purchased products specification and the products specification to be purchased are shown. If the purchaser selects the product of which the purchasing specification is to be identified (step S630), various purchasing condition input sheets are provided (step S640). At that time, if various purchasing conditions are modified (step S650), the products satisfaction index (PSI) is computed depending upon various modified purchasing conditions (step S660). If the purchasing satisfaction condition (PSP) is computed (step S670), the product retrieve is performed (step S680), and the comparative specification is outputted on the screen (step S690). In case of approving the purchase for the product, which is not purchased at present but is latently purchased, contained in a temporary keeping box (e.g., putting in a shopping basket), the information related to the product is stored in the purchasing specification database, and may be reused when purchasing the product after this or repurchasing the purchased product.

[000119] One preferred embodiment of the present invention will now be described with reference to Figs. 10 to 17.

[000120] Fig. 10 shows an example of an initial screen displayed on a display unit of the seller or the purchaser.

[000121] The initial screen includes an input item 10, a retrieve item 20, and a purchasing specification inquiring item 30. The input item is allocated with a member information input button 12, a products information input button 14, and a purchasing condition input button 16. The retrieve item 20 is allocated with a retrieve button 22 for the products satisfaction index, a retrieve button 24 for the priority of the purchasing condition, and a retrieve button 26 for a single purchasing condition. The purchasing specification inquiring item 30 is allocated with a purchased products specification inquiring button 32 and a purchasing products specification inquiring button 34.

[000122] If the member information input button 12 is selected, the member joining of the purchaser or the seller is achieved or it may identify whether to be a member or not.

[000123] If the products information input button 14 is selected, the request of products information registration is displayed, as shown in Fig. 11A, the request of products information registration including a selling price, the sale approval price according to the products satisfaction index, and items to be contained in various purchasing conditions.

[000124] The purchase approval is determined depending upon the sale approval price when the purchaser represents the purchasing satisfaction condition. The sale approval price according to the products satisfaction index is provided in the type shown in Fig. 11B. If the seller inputs a discount rate suitable to the price policy of the seller on a blank of discount rate, the minimum sale approval price is computed. By properly utilizing it, the latent purchasing client can be directly connected to the purchase.

[000125] "Whether or not a product set" and "construction of set" items are used at a multiple retrieve, and in the embodiment of the present invention the construction of set includes shirt/shirt, shirt/trousers, shirt/cardigan, and

shirt/tie. The purchaser may retrieve the trousers, cardigan, and tie, simultaneously.

[000126] A “comparative dominant item” is to compute the products satisfaction index according to the weight applying method. Specifically, the products satisfaction index is computed by comparing the comparative dominant item with the products selection criteria item of the purchaser and weighting the purchasing condition item related thereto.

[000127] If the products information is inputted and a registration button is pushed, as shown in Fig. 11A, each item of the contents and the contents of the particulars are stored in the products information database of the operator. In order to input the updated products information, if the seller pushes the modifying button and inputs an ID, a brand and a model number, the data previously inputted is displayed, and the modification is achieved herein. A cancel button is used to cancel the inputted products information.

[000128] Fig. 11A shows one embodiment of the present invention, in which the ID of the seller is kmix. The seller inputs the products information of a men’s shirt, of which it is suitable to an age from 18 years old to 50 years old, the selling price is 53,000 won, and its model number is C5896. It will be seen that the quality of the product is a comparative predominant over the others.

[000129] If the purchasing condition input button 16 is clicked, as shown in Fig. 12A, the basic purchasing condition input sheet is provided. If the purchaser inputs the brand, the basic purchasing condition items related to the product is displayed on the input sheet. The purchaser inputs the purchasing condition and pushes a general retrieve button to carry on retrieve.

[000130] Meanwhile, if the purchaser pushes a detailed retrieve button to obtain the products satisfaction index or the purchasing satisfaction condition, the detailed purchasing condition input sheet in Fig. 12C is provided. If the input is completed, the products satisfaction index and the purchasing satisfaction condition are computed and the results of the product retrieve are displayed on the screen.

[000131] Referring to Fig. 12C, the “construction of set” item is activated in case of needing the set in the basic purchasing condition input sheet of Fig. 12A, or is inactivated in case of no requiring the set. Meanwhile, the products information suitable to various purchasing conditions of the basic purchasing condition input sheet is provided as shown in Fig. 12B. If the product retrieve is required depending upon the purchasing condition, some items of the detailed purchasing conditions are applied and displayed as the contents of the products information. If it does not required, the purchaser selects each item of the detailed purchasing condition input sheet according to the purchase propensity.

[000132] In the detailed purchasing condition input sheet shown in Fig. 12C, a color is beige among four colors, a brightness is bright, a chroma is light, a pattern is no between two patterns, and a shape of a neck is V-shape, in the contents of the products information of Fig. 12B. By way of provisions against an occasion that the purchaser does not know how does it input due to the insufficiency of preliminary information on the product to be purchased by the purchaser, it makes the product selection to be ease, and it is possible to shorten a time required for inputting various purchasing conditions.

[000133] If the input of the detailed purchasing condition is completed and a confirming button is pushed, the products satisfaction index and the purchasing satisfaction condition are computed, and the product retrieve is

performed. In order to modify the inputted contents, a modify button is pushed, and the cancel button is pushed to cancel the inputted contents.

[000134] Figs. 12A and 12C show one embodiment of the present invention, in which a purchaser having an ID called kkkk inputs the purchasing condition to retrieve a men's shirt in a range of 40,000 won to 60,000 won. The contents of the basic and detailed input sheets in Figs. 12A and 12C are substantially similar to those of the request of products information registration of Fig. 11A.

[000135] In case of selecting and inputting the particulars for each item of the request of products information registration, and the basic and detailed purchasing condition input sheets, in Fig. 11A, Figs. 12A and 12C, the input is performed by a radio button input manner selecting one by pushing a button ☐, a check input manner marking a symbol ☒ in case of simultaneously selecting and inputting two or more particulars, or a number input manner appointing numbers to the particulars and selecting a corresponding content by the seller or the purchaser in case of inputting the purchasing condition requiring the weight or order.

[000136] If the input is completed, the products information system extracts the products suitable for the product name and price condition, which are the first retrieve condition, and computes the products satisfaction index and the purchasing satisfaction condition of the group of the products. In particular, the purchaser having an ID called kkkk selects a "quality" item among the product selection criteria items. The purchasing conditions related to the quality includes "price", "origin", "product material", "wrinkle-free", and "sweat absorption", in case of the shirt, as can be seen from a classification table of purchasing conditions related to the products selection criteria items of Fig. 13. It will be seen that the items of "price", "origin", "wrinkle-free", and "sweat absorption" are identical to the items of "price", "origin", "wrinkle-free",

and "sweat absorption" in the request of products information registration of the seller in Fig. 11A, with the comparative item being the quality in each other. It will be seen that the "product material" is different from each other, for example, mixed spinning and cotton. When the operator makes the purchasing condition database, the classification table related to the whole products is prepared as an example of Fig. 13, and is applied when computing the products satisfaction index based on the weight.

[000137] The products satisfaction index may be computed by use of the weight applying method of the equation 3 as below to identify how does a product model C5896 satisfy the purchasing condition of the purchaser.

[000138] In the products satisfaction index $Is = \{ (xNcs + Nct) / (xNs + (Nt - Ns)) \} \times 100$, the total purchasing condition items of the purchaser, Nt , is 32 items among the purchasing conditions of the purchaser, except a product user and the product selection criteria. Whether the product user is the person himself or herself is not important to compute the products satisfaction index. Since the item of product selection criteria is used to apply the weight, the above two items are excluded from the total of items.

[000139] The number of purchasing condition items, Ns , related to the "predominant item" of the products information database and the "product selection criteria" items among the purchasing condition items includes five items such as "price", "origin", "product material", "wrinkle-free", and "sweat absorption". The number of the purchasing conditions, Ncs , in case that the contents of "predominant item" of the products information database is identical to that of the item of "product selection criteria" among the purchasing condition items includes four items such as "price", "origin", "wrinkle-free", and "sweat absorption". The number of the purchasing condition items, Nct , in case that the contents of "predominant item" of the products information database is no identical to that of the item of "product

selection criteria” among the purchasing condition items includes 26 items except whether to have a pocket or not. The weight, x , on each item of which the contents is identical between the number of purchasing condition items related to the “predominant item” of the products information database and the “product selection criteria” items among the purchasing condition items is applied twice as much as the common item. It is determined by the operator, and a deviation of the products satisfaction index is increased by raising the weight for the product similar to the characteristic or property of the product or the purchasing condition, thereby making the product retrieve to be easy.

[000140] Computing the products satisfaction index based on the weight applying method, in $Is = \{ (xNcs + Nct) / (xNs + (Nt - Ns)) \} \times 100$, $Is = \{ ((2 \times 4) + 26) / (2 \times 5) + (32 - 5) \} \times 100 \text{ ® } 91.9(\%)$. Accordingly, the product model C5896 is 91.9% of Is , and thus satisfies to the purchasing condition of the purchaser having the ID of kkkk.

[000141] Computing the products dissatisfaction index using the equation 4, since it is represented as the results by subtracting the products satisfaction index (Is) from 100 of the maximum products satisfaction index, $Iu = (Nu / Nt) \times 100 = 100 - Is = 100 - 91.9 \text{ ® } 8.1(\%)$. The product having about 8.1% of Iu does not satisfy to the products satisfaction index of the purchaser.

[000142] Next, computing the purchasing satisfaction condition using the equation 5, since in $Psp = Ps \times Is$, the selling price (Ps) of individual product is 53,000 won, and the products satisfaction index (Is) is 91.9%, $Psp = 53,000 \times 91.9\% \text{ ® } 48,700$ won. In addition, computing the purchasing satisfaction condition based on the products dissatisfaction index, since the reduced price (Pr) is a price computed by multiplying 53,000 won of the selling price (Ps) by 8.1% of the products dissatisfaction index (Iu), $Pr = Ps \times Iu / 100 = 53,000 \times 8.1\% \text{ ® } 4,300$ won. Accordingly, since the purchasing

satisfaction condition is a price computed by reducing the selling price by a part corresponding to the dissatisfaction of the purchaser to the product, $P_{sp} = P_s - P_r = 53,000 - 4,300 = 48,700$ won.

[000143] If the first product retrieve is completed and the products satisfaction index and the purchasing satisfaction condition are determined, the final product retrieve is performed in the retrieving items.

[000144] If a retrieve button 22 for the products satisfaction index is clicked, a message to input a value on a value inputting blank 23 of the products satisfaction index is displayed. If the purchaser inputs a value of the products satisfaction index to be retrieved and pushes the retrieve button, the products which belong to a range of the products satisfaction index more than the value are arranged and displayed. If necessary, the purchaser may modify and retrieve the value of the products satisfaction index at any time.

[000145] The purchaser clicks a retrieve button 24 for the priority of the purchasing conditions, items of the purchasing condition input sheet prepared by inputting the purchasing conditions with the purchaser and the contents 241 the particulars selected to the item are displayed. The purchaser drags and fills in order the items determined in accordance with the priority. Alternatively, the purchaser may provide the items of the purchasing condition input sheet with serial numbers, and inputs in order the corresponding number of the item in the input blank 242 in accordance with the priority. Fig. 14A shows the priority of the purchasing condition determined and inputted by the purchaser kkkk, in which five priorities are inputted in the embodiment of the present invention, but may be modified depending upon the kind or characteristic of the product and the environment of the operator. If the priorities are inputted, the products are rearranged depending upon the order of the priorities, so that the purchaser can retrieve accurately the required target product.

[000146] If the purchaser clicks the retrieve button 26 for a single purchasing condition, items of the purchasing condition input sheet prepared by inputting the purchasing conditions with the purchaser and the contents 242 the particulars selected to the item are displayed. If the purchaser selects one among the items, the contents is displayed on the screen. For one example, if the "product material" item is selected in Fig. 14A, the contents 83 related to the product material of each product is displayed on the screen as shown in Fig. 14B. Thus, the purchaser can compare the products in accordance with each purchasing condition. Alternatively, the system may retrieve the products in various manners based on the retrieving criteria such as products dissatisfaction index and selling price, as well as retrieving the product based on the priority of the purchasing conditions or products satisfaction index. Since the operator process the products information in accordance with various purchasing conditions of the purchaser, the operator can provide the seller with various marketing related information such as a sex, an age group, a propensity to purchase and so forth.

[000147] Referring to Fig. 10, the product name among the purchasing conditions inputted by the purchaser is displayed in a product name item 40, and the minimum price condition and the maximum price condition among the purchasing conditions inputted by the purchaser are displayed in a price item 50.

[000148] A view item 70 includes an image view button 72 and a comparative specification view item 74. If is used by the purchaser to view the retrieved results using the screen consisting of a product image and the products satisfaction index or the screen consisting of the comparative specification. For one example, if the image view button 72 is clicked, the product image or moving picture 82 is displayed as a checked-arranging screen 80, together with the products satisfaction index (PSI) and the purchasing satisfaction condition (PSP) 84. Nine screens from D1 to D9 are

provided in Fig. 10, but the number of the screens may be regulated depending upon the environment of the operator. Such the checked-arranging screen has some advantages in that the purchaser can compare the group of retrieved product together with the products satisfaction index, and can easily find the target product by considering the products in order of magnitude of the products satisfaction index. The checked-arrangement can provide several effects in that the operation of various games using the product screen may arouse an interest in the purchaser, and the sales effect may be increased by offering premiums. Under the checked-arranging screen, there are a previous page shift arrow 86 and a next page shift arrow 88 so as to easily shift the page.

[000149] If the comparative specification view button 74 is clicked, the retrieve results are displayed as the comparative specification on the basis of the products satisfaction index, and the checked-arranging screen is disappeared. Again click the image view button 72, the checked-arrangement is appeared. However high the products satisfaction index, there is a case in that it does not satisfy the purchasing condition to be considered by the purchaser himself/herself. At that time, by previously considering dissatisfaction factors of the product having the high products satisfaction index in the comparative specification, the target production may be more correctly found when determining the priority of the purchasing condition items.

[000150] The product retrieve results of the purchaser are shown as an comparative specification in Fig. 15A, in which only products having above 70% of the products satisfaction index inputted by purchaser himself/herself in Fig. 14A are displayed, and it is shown in that the products satisfaction index of the product model A3589 is 93.7%. In the embodiment of the present invention, the purchaser kkkk inputs in the input blank 242 items among several purchasing conditions as shown in Fig. 14A in the order of priority, for

example, a product having high brand perception at the first priority, a self-supplied product at the second priority, a up-to-date product at the thirdly priority, a product having no design at fourth priority, and a product having no wrinkle at the fifth priority. Since the product model A3589 does not coincide with the product required by the purchaser kkkk who considers the brand perception as the first priority, it does not regard as the target product. As would be seen from the comparative specification arranged based on the priorities of the purchasing condition in Fig. 15B, the product C5896 having 91.9% of the products satisfaction index is appropriate to the purchaser kkkk. Accordingly, the utilization of the product dissatisfaction factor of the comparative specification and the priorities of the purchasing conditions may cause target product to be most exactly found. Of course, upon making a decision over the purchase, since the purchasing conditions of the purchaser are always changed, the product model No. A3589 may be appropriate to the purchaser kkkk.

[000151] The electric commerce is achieved after the products information retrieve is completed. Specifically, if the purchaser moves the cursor onto the screen of the product to be purchased among the retrieved products, and pushes a purchase button 60. The purchase approval module determines whether the purchasing satisfaction condition of the selected product belongs to the range of the sale approval price of the seller, and displays the results of the purchase approval on the screen.

[000152] For example, when the purchaser kkkk purchases the product C5896 having 91.9% of the products satisfaction index, 48,700 won of the purchasing satisfaction condition of the product is a purchase offering price, while the sale approval price according to the products satisfaction index of the products information database belongs to a range from 50,615 won to 53,000 won. The product is not obtained permission to be automatically purchased for 48,700 won. If the purchaser wants to purchase

the product, since the products satisfaction index is 91.9% as shown in Fig. 11B, the selling price of 50,615 won (the minimum sale approval price for 91 to 95% of the products satisfaction index) which is reduced the price by 4.5% is displayed from the products information database. At that time, if the purchaser regards the price as a proper price, the purchaser may purchase it. 48,700 won which is the purchase proposal price by the purchaser and 50,615 won which is the final sales proposal price of the seller are a chaffering price. If the purchaser makes a decision over the purchase, the product is transferred to the purchaser, while the seller has an order to deliver the product to the purchaser.

[000153] Fig. 16 shows a multiple retrieving method according to the present invention.

[000154] If a product set 90 consists of a shirt and a tie, there are three cases: first, the purchaser satisfies the shirt, but wants to select other tie; secondly, how does the tie satisfy the purchasing condition of the purchaser, in other word, the purchaser wants to know the products satisfaction index; and, finally, the purchaser wants to further retrieve other tie on the basis of the corresponding tie, for example, whether there is other tie more better than it.

[000155] In the prior case, however, after the purchaser has to purchase the shirt, the purchaser again retrieves and selects other tie from the beginning. According to the present invention, the purchaser can retrieve other tie, with the product called shirt be left alone. Specifically, in state of selecting the shirt, if a product name 94 called tie is clicked, the contents of the inherent products information on the basic purchasing condition and the detailed purchasing condition for the tie, i.e., the basic purchasing condition input sheet and the detailed purchasing condition input sheet each supplied with an initial value, are provided. At that time, the purchaser selects and

inputs the condition suitable for the items with no given value to each purchasing condition item. And then, if the purchaser revises and inputs items suitable for the purchasing condition of his/her, the products satisfaction index and the purchasing satisfaction condition are computed, and other similar retrieved products proper to the condition are displayed. At that time, the purchaser may select other similar retrieved products suitable to his/her taste on the basis of the image of the shirt.

[000156] The routine of selecting the shirt and then the tie matching with the shirt through the above processes may be easily performed by a multitasking.

[000157] This is possible because when inputting the information of the product set of the seller the product name and the price range are separately classified by the kind of the products and are stored in the products information database, and because only the products near to the purchasing condition of the purchaser are displayed on the basis of the value called the products satisfaction index.

[000158] Referring to Fig. 17, in case that a button 32 for referring the products specification purchased or a button 34 for referring the products specification to be purchased is clicked on the initial screen, a table 321 containing much information is displayed. The button 32 for referring the products specification purchased is used to review the products specification previously purchased for again purchase it, and the button 34 for referring the products specification to be purchased is used to review the information newly replaced by the updated data by reading in the products specifications which are not decided to purchase in the past and are stored in the temporary keeping box. At that time, if one product is selected among the products displayed, the information related to the product is displayed.

[000159] The present invention constructed as described above has some advantages.

[000160] First, since the purchaser retrieves the product by use of only one value called the products satisfaction index, it is possible to find the target product easily, quickly and correctly. In particular, the products satisfaction index becomes substantial information because of reflecting simultaneously the comparative dominant item to the product to be sold by the seller and the products selection criteria item of the purchaser.

[000161] In addition, the more effective product retrieve may be performed by showing the product dissatisfaction factors in the comparative specification, and the target product can be correctly retrieved on the basis of various purchasing conditions for the group of the retrieve products.

[000162] The product purchase may be easily performed since the related products are retrieved through the multiple retrieve.

[000163] Furthermore, the purchase satisfaction can be obtained due to the purchasing satisfaction condition computed based on the products satisfaction index, and since the products dissatisfaction index is converted into the reduced price the purchaser can obtain the purchase satisfaction.

[000164] Since the purchasing satisfaction condition and the sale approval price are automatically changed, the seller can be absolutely relieved of a burden to the price competition with the products manufactured by other company. By the utilization of the minimum sale approval price based on the products satisfaction index, a latent purchasing client can be directly connected to the purchase. In particular, since the purchaser can retrieve extensive products, it is easy to sell the related products in addition to the product to be retrieved by the purchaser. Also, because various

purchasing conditions of the purchaser are applied to the product, it can be easily set up a marketing plan, and it can reduce various expenses. Sales are promoted by compensating the products dissatisfaction index of the purchaser with the reduced price.

[000165] The number of members is increased by providing the purchaser with the convenient retrieving method, and accordingly, the increase of the advertising revenue and effective marketing are possible. Since it is easy to sell the related products through the multiple retrieve, the sale is more increased. In addition, the product retrieve is directly connected to the purchase through the products satisfaction index and the purchasing satisfaction condition. An intermediary profit may be increased by the sales promotion because of carrying out the electric commerce in real time. Furthermore, since various purchasing conditions of the purchaser are applied to the sales product of the seller, statistical data and information usable in the object economy may be provided to the manufactures, the producers, the distributors and other company starting a new business.
